Abstract. In this paper we show how Einstein metrics are naturally described using the quantization of the algebra of functions $C^\infty(M)$ on a Kähler manifold M . In this setup one interprets M as the phase space itself, equipped with the Poisson brackets inherited from the Kähler 2-form. We compare the geometric quantization framework with several deformation quantization approaches. We find that the *balanced metrics* appear naturally as a result of requiring the vacuum energy to be the constant function on the moduli space of *semiclassical vacua*. In the classical limit these metrics become Kähler–Einstein (when M admits such metrics). Finally, we sketch several applications of this formalism, such as explicit constructions of special Lagrangian submanifolds in compact Calabi–Yau manifolds.

Key words: balanced metrics, geometric quantization, Kähler–Einstein

1 Introduction

Noncommutative deformations of Kähler geometry exhibit some extraordinary features, similar to those that appear in the description of n quantum harmonic oscillators by the noncommutative phase space \mathbb{C}^n . Noncommutative geometry in Calabi–Yau compactifications is expected to play a special role when the B -field is turned on [21, 15], in the formulation of M(atr)ix theory [3, 7, 14], and in the large N limit of probe D0-branes [13]. Also, as we show below, one can use the geometric quantization approach to noncommutative geometry to determine¹ important objects in string theory compactifications, which allow the computation of the exact form of the Lagrangian in the four dimensional effective field theory [8, 9, 10, 11].

In this paper we show how the notion of *balanced metrics* appears naturally in the framework of Kähler quantization/noncommutative geometry. In the geometric quantization formalism the balanced metric appears as a consequence of requiring the norm of the coherent states to be constant; these states are parameterized by the Kodaira’s embedding of the Kähler manifold M into the projectivized quantum Hilbert space. In the Reshetikhin–Takhtajan approach to the deformation quantization of M [20], the balanced metric appears as a consequence of requiring the unit of the quantized algebra of functions $C^\infty(M)[[\hbar]]$ to be the constant function $\mathbf{1}: M \rightarrow 1 \in \mathbb{R}$. Finally, we quantize the phase space with constant classical Hamiltonian on M using the path integral formalism; here, one considers a different class of semiclassical vacuum states which are not coherent states, and uses them to define² a generalization of the balanced metrics (which also become Einstein metrics in the *classical limit*).

*This paper is a contribution to the Special Issue “Noncommutative Spaces and Fields”. The full collection is available at <http://www.emis.de/journals/SIGMA/noncommutative.html>

¹More precisely, what one can determine are certain metrics, known as balanced metrics, which obey the equations of motion in the classical limit.

²By requiring the vacuum energy density to be the constant function on the semiclassical vacua, labeled by the points $x \in M$.

The organization of the paper is as follows. In Section 2 we recall some basic facts of geometric quantization [2, 12, 22], show how the balanced metrics appear naturally in this framework, and sketch how differential geometric objects, such as Kähler–Einstein metrics or Lagrangian submanifolds, can be described in this language. In Section 3 we summarize the work of Reshetikhin–Takhtajan, and show how the constant function is the unit element of their quantized algebra of functions if and only if the metric on M is balanced. Finally, in Section 4 we consider a different set of semiclassical vacuum states in path integral quantization and use them to define *generalized balanced metrics*, which differ slightly from the balanced metrics in geometric quantization.

2 Geometric quantization

Classical mechanics and geometric quantization have a beautiful formulation using the language of symplectic geometry, vector bundles, and operator algebras [2, 12, 22]. In this language, symplectic manifolds M are interpreted as phase spaces, and spaces of smooth functions $C^\infty(M)$ as the corresponding classical observables.

Kähler quantization is understood far better than quantization on general symplectic manifolds; for this reason we only consider Kähler manifolds (which are symplectic manifolds endowed with a compatible complex structure). $(M, \mathcal{L}^{\otimes \kappa})$ denotes a polarized Kähler manifold M with a very ample hermitian line bundle³ $\mathcal{L}^{\otimes \kappa}$, and $\kappa \in \mathbb{Z}_+$ a positive integer. For technical reasons, we consider M to be compact and simply connected. We work with a trivialization of $\mathcal{L}|_U \rightarrow U$, where $U \subset M$ is an open subset; we define $K(\phi, \bar{\phi})$ to be the associated analytic Kähler potential and $e^{-\kappa K(\phi, \bar{\phi})}$ the hermitian metric on $\mathcal{L}^{\otimes \kappa} \rightarrow M$. If $\dim_{\mathbb{C}} M = n$ and $\{\phi_i\}_{0 < i \leq n}$ is a local holomorphic coordinate chart for the open subset $U \subset M$, we can write the Kähler metric on M and its compatible symplectic form as

$$i\kappa g_{i\bar{j}} d\phi^i \otimes d\bar{\phi}^{\bar{j}} = \kappa \omega_{i\bar{j}} d\phi^i \wedge d\bar{\phi}^{\bar{j}} = i\kappa \frac{\partial}{\partial \phi^i} \frac{\partial}{\partial \bar{\phi}^{\bar{j}}} K(\phi, \bar{\phi}) d\phi^i \otimes d\bar{\phi}^{\bar{j}}.$$

Classically, the space $(C^\infty(M), \omega)$ of observables has, in addition to a Lie algebra structure defined by the Poisson bracket

$$\{f, g\}_{PB} = \omega^{i\bar{j}} (\partial_i f \bar{\partial}_{\bar{j}} g - \partial_i g \bar{\partial}_{\bar{j}} f), \quad f, g \in C^\infty(M),$$

the structure of a commutative algebra under pointwise multiplication,

$$(fg)(x) = f(x)g(x) = (gf)(x).$$

Quantization can be understood as a non-commutative deformation of $C^\infty(M)$ parameterized by \hbar , with commutativity recovered when $\hbar = 0$. We will discuss the formalism of deformation quantization in the next section, although generally speaking, quantization refers to an assignment $T: f \rightarrow T(f)$ of classical observables to operators on some Hilbert space \mathcal{H} . When M is compact, the Hilbert space will be finite-dimensional with dimension $\dim \mathcal{H} = \frac{\text{vol } M}{\hbar^n} + O(\hbar^{1-n})$. The assignment T must satisfy the following requirements:

- Linearity, $T(af + g) = aT(f) + T(g)$, $\forall a \in \mathbb{C}$, $f, g \in C^\infty(M)$.
- Constant map 1 is mapped to the identity operator Id , $T(1) = \text{Id}$.
- If f is a real function, $T(f)$ is a hermitian operator.
- In the limit $\hbar \rightarrow 0$, the Poisson algebra is recovered $[T(f), T(g)] = i\hbar T(\{f, g\}_{PB}) + O(\hbar^2)$.

³In other words, $\mathcal{L}^{\otimes \kappa}$ is an element of the Kähler cone associated to M .

In geometric quantization the positive line bundle $\mathcal{L}^{\otimes \kappa}$ is known as *prequantum line bundle*. The prequantum line bundle is endowed with a unitary connection whose curvature is the symplectic form $\kappa\omega$ (which is quantized, i.e., $\omega \in H^2(M, \mathbb{Z})$). The *prequantum Hilbert space* is the space of L^2 sections

$$L^2(\mathcal{L}^{\otimes \kappa}, M) = \left\{ s \in \Omega^0(\mathcal{L}^{\otimes \kappa}) : \int_M h^\kappa \langle s, \bar{s} \rangle \frac{\omega^n}{n!} < \infty \right\},$$

where h^κ is the compatible hermitian metric on $\mathcal{L}^{\otimes \kappa}$. The Hilbert space is merely a subspace of $L^2(\mathcal{L}^{\otimes \kappa}, M)$, defined with the choice of a polarization on M . In the case of Kähler polarization, the split of the tangent space in holomorphic and anti-holomorphic directions, $TM = TM^{(1,0)} \oplus TM^{(0,1)}$, defines a Dolbeault operator on $\mathcal{L}^{\otimes \kappa}$, $\bar{\partial}: \Omega^{(0)}(\mathcal{L}^{\otimes \kappa}) \rightarrow \Omega^{(0,1)}(\mathcal{L}^{\otimes \kappa})$. The Hilbert space \mathcal{H}_κ is only the kernel of $\bar{\partial}$, i.e., the space of holomorphic sections $H^0(M, \mathcal{L}^{\otimes \kappa})$.

As a final remark, the quantization map T is not uniquely defined; there are different assignments of smooth functions on M to matrices on \mathcal{H}_κ that obey the same requirements stated above, giving rise to equivalent classical limits. For simplicity, we mention only the most standard ones [4]:

- *The Toeplitz map:* $T(f)_{\alpha\bar{\beta}} = \int_M f(z, \bar{z}) s_\alpha(z) \bar{s}_\beta(\bar{z}) h^\kappa(z, \bar{z}) \frac{\omega(z, \bar{z})^n}{n!}$, with s_α a basis of sections for \mathcal{H}_κ and $s_\alpha(z)$ the corresponding evaluation of s_α at $z \in U \subset M$.
- *The geometric quantization map:* $Q(f) = iT(f - \frac{1}{2}\Delta f)$, with Δ the corresponding Laplacian on M .

We will work only with completely degenerated Hamiltonian systems (i.e. a constant Hamiltonian function on M); therefore the choice of quantization map will not be important. Rather we will study the semiclassical limit of the corresponding quantized system by determining the semiclassical vacuum states.

2.1 Coherent states and balanced metrics

As we described above, the geometric quantization picture is characterized by the prequantum line bundle, $\mathcal{L}^{\otimes \kappa} \rightarrow M$, a holomorphic line bundle on M which is endowed with a $U(1)$ connection with Kähler 2-forms $\kappa\omega$. As the positive integer κ always appears multiplying the symplectic form, one can interpret $\kappa^{-1} = \hbar$ as a discretized Planck's constant. Thus, according to this convention, the semiclassical appears in the limit $\kappa \rightarrow \infty$.

In the local trivialization $U \subset M$, where $K(\phi, \bar{\phi})$ is the Kähler potential and $e^{-\kappa K(\phi, \bar{\phi})}$ the hermitian metric on $\mathcal{L}^{\otimes \kappa}|_U$, one can set the compatible Dolbeault operator to be locally trivial and write the covariant derivative as

$$\tilde{\nabla} = d\phi^i (\partial_i - \kappa \partial_i K) + d\bar{\phi}^{\bar{i}} \bar{\partial}_{\bar{i}},$$

where K is the yet undetermined analytic Kähler potential on \mathcal{L} . One can also determine the associated unitary connection up to a $U(1)$ gauge transformation,

$$\nabla = d\phi^i (\partial_i + A_i) + d\bar{\phi}^{\bar{i}} (\bar{\partial}_{\bar{i}} - A_{\bar{i}}^\dagger),$$

with $A_i = \sqrt{\hbar^{-\kappa}} \partial_i \sqrt{\hbar^\kappa}$, and $h = \exp(-K(\phi, \bar{\phi}))$.

As explained above, the Hilbert space \mathcal{H}_κ corresponds to the kernel of the covariant half-derivative $\nabla^{(0,1)}: \Omega^{(0)}(\mathcal{L}) \rightarrow \Omega^{(0,1)}(\mathcal{L})$, which are the holomorphic sections of $\mathcal{L}^{\otimes \kappa}$

$$\mathcal{H}_\kappa = H^0(M, \mathcal{L}^{\otimes \kappa}) = \text{span}_{\mathbb{C}} \{ |s_\alpha\rangle \}_{\alpha=1}^N.$$

The dimension of the quantum Hilbert space is

$$N = \dim \mathcal{H}_\kappa = \frac{1}{n!} \int_M c_1(\mathcal{L})^n \kappa^n + \frac{1}{2(n-1)!} \int_M c_1(\mathcal{L})^{n-1} c_1(M) \kappa^{n-1} + O(\kappa^{n-2}).$$

We identify $|s_\alpha\rangle$ as the basis elements of \mathcal{H}_κ . The *coherent state* localized at $x \in M$ can be defined (see [19]) on the trivialization $\mathcal{L}^{\otimes \kappa}|_U \rightarrow U \subset M$ as the ray in $\mathbb{P}\mathcal{H}_\kappa$ generated by

$$|\tilde{\Omega}_x\rangle = \sum_\alpha s_\alpha(x) \exp(-\kappa K(x, \bar{x})/2) |s_\alpha\rangle \in \mathcal{H}_\kappa,$$

where $s_\alpha(x) \exp(-\kappa K(x, \bar{x})/2)$ is the evaluation of the holomorphic section $|s_\alpha\rangle$ at the point $x \in U \subset M$, in the trivialization $\mathcal{L}^{\otimes \kappa}|_U$. The coherent states are a supercomplete basis of \mathcal{H}_κ , and obey the Parseval identity

$$\langle \zeta | \xi \rangle = \int_{M \mapsto \mathbb{P}\mathcal{H}_\kappa} \langle \zeta | \tilde{\Omega}_x \rangle \langle \tilde{\Omega}_x | \xi \rangle \frac{\omega^n(x, \bar{x})}{n!}, \quad \forall \zeta, \xi \in \mathcal{H}_\kappa. \quad (1)$$

These points in $\mathbb{P}\mathcal{H}_\kappa$ are independent of the trivialization, and they have the property of being localized at $x \in M$ with minimal quantum uncertainty. The *distortion function*, diagonal of the Bergman kernel, or expected value of the identity at x , $\rho(x, \bar{x})$ is defined as

$$\rho = \langle \tilde{\Omega}_x | \tilde{\Omega}_x \rangle = \sum_{\alpha, \beta} \bar{s}_\alpha(\bar{x}) s_\beta(x) \exp(-\kappa K(x, \bar{x})) \langle s_\alpha | s_\beta \rangle, \quad (2)$$

which measures the relative normalization of the coherent states located at different points of M . Imposing $\rho(x, \bar{x}) = \langle \tilde{\Omega}_x | \tilde{\Omega}_x \rangle = \text{const}$, constrains the Kähler potential $K(x, \bar{x})$ to be a Fubini–Study Kähler potential:

$$K(x, \bar{x}) = \frac{1}{\kappa} \log \left(\sum_{\alpha, \beta} \bar{s}_\alpha(\bar{x}) s_\beta(x) \langle s_\alpha | s_\beta \rangle \right). \quad (3)$$

One of the most important ingredients in the quantization procedure is the definition of the quantization map, $T : C^\infty(M) \rightarrow \text{Herm}(\mathcal{H}_\kappa)$. This maps classical observables, i.e. smooth real functions on the phase space X , to quantum observables, i.e., self-adjoint operators on the Hilbert space \mathcal{H}_κ . If we work with an orthonormal basis $\langle s_\beta | s_\alpha \rangle = \delta_{\beta\alpha}$, the quantization condition

$$T(1_M) = \text{Id} \in \mathcal{H}_\kappa \otimes \mathcal{H}_\kappa^*$$

implies that the embedding of the coherent states satisfies the *balanced* condition [9],

$$\delta_{\alpha\beta} = \langle s_\alpha | s_\beta \rangle = \sum_x \langle s_\alpha | \tilde{\Omega}_x \rangle \langle \tilde{\Omega}_x | s_\beta \rangle = \int_M \frac{\bar{s}_\alpha(\bar{x}) s_\beta(x) \omega(x, \bar{x})^n}{\sum_\gamma |s_\gamma(x)|^2 n!}; \quad (4)$$

here, we have used the Parseval identity (1), and the Liouville's volume form on the phase space M , which can be written as

$$\frac{1}{n!} \omega(z, \bar{z})^n = \frac{1}{n!} [\bar{\partial}_j \partial_i K(z, \bar{z}) dz^i \wedge d\bar{z}^j]^n.$$

In summary, in the geometric quantization of an algebraic Kähler manifold, the homogeneity of the distortion function $\langle \tilde{\Omega}_x | \tilde{\Omega}_x \rangle$ and the mapping of the constant function on M to the identity operator $\text{Id} : \mathcal{H}_\kappa \rightarrow \mathcal{H}_\kappa$, determines a unique metric on M known as *balanced metric*. In the semiclassical limit, $\kappa \rightarrow \infty$, this sequence of balanced metrics approaches the Kähler–Einstein metric (if it exists) as sketched below (see [8, 11]).

2.2 Emergence of classical geometry

For every κ , the *balanced metric* has just been defined as result of requiring $\langle \tilde{\Omega}_x | \tilde{\Omega}_x \rangle$ to be the constant function on M . In the semiclassical limit, $\kappa \rightarrow \infty$, we can expand the distortion function in inverse powers of κ (see [23])

$$\langle \tilde{\Omega}_{x,\kappa} | \tilde{\Omega}_{x,\kappa} \rangle \sim 1 + \frac{1}{2\kappa} R + O(\kappa^{-2}) + \dots,$$

and therefore the sequence of balanced metrics will converge to a metric of constant scalar curvature at $\kappa = \infty$. For a Calabi–Yau manifold this is equivalent to a Ricci flat Kähler metric. It is interesting to note that if the identity matrix is identified with the quantum Hamiltonian, and the coherent states with the semiclassical states, the *balanced metric* can also be defined as the metric that yields a constant semiclassical vacuum energy $\langle \tilde{\Omega}_{x,\kappa} | \tilde{\Omega}_{x,\kappa} \rangle$, as a function of $x \in M$ and fixed κ .

Other geometrical elements that one can recover naturally are the Lagrangian submanifolds with respect the Kähler–Einstein symplectic form. In the Kähler n -fold (M, ω) , the level sets of n commuting functions (f_1, f_2, \dots, f_n) under the Poisson bracket

$$\{f_a, f_b\}_{PB} = \omega^{i\bar{j}}(\partial_i f_a \bar{\partial}_j f_b - \partial_i f_b \bar{\partial}_j f_a) = 0, \quad \forall a, b,$$

define a foliation by Lagrangian submanifolds. One can recover such commutation relations as the classical limit of n commuting self-adjoint operators on the Hilbert space \mathcal{H}_κ [4]:

$$\langle \tilde{\Omega}_{x,\kappa} | [\hat{f}_a, \hat{f}_b] | \tilde{\Omega}_{x,\kappa} \rangle \sim \frac{i}{\kappa} \{f_a, f_b\}_{PB} + O(\kappa^{-2}),$$

with $\langle \tilde{\Omega}_{x,\kappa} | \hat{f}_a | \tilde{\Omega}_{x,\kappa} \rangle \rightarrow f_a(x)$, and $|\tilde{\Omega}_{x,\kappa}\rangle$ the coherent state peaked at $x \in X$. Thus, one can approximate Lagrangian submanifolds by using n -tuples of commuting matrices for large enough κ . One can impose further conditions, i.e. $\text{Im}(\Omega)|_{\text{SLag}} = 0$, in order to describe special Lagrangian submanifolds. More precisely, we define the quantum operator

$$\begin{aligned} \mathcal{I}_{\bar{\alpha}\beta\bar{\alpha}_1\beta_1\dots\bar{\alpha}_n\beta_n} &= \frac{1}{2i} \int_M \frac{\omega^n}{n!} \bar{s}_{\bar{\alpha}} s_\beta e^{-\kappa K} \left(\Omega_{i_1\dots i_n} \partial^{i_1} (\bar{s}_{\bar{\alpha}_1} s_{\beta_1} e^{-\kappa K}) \dots \partial^{i_n} (\bar{s}_{\bar{\alpha}_n} s_{\beta_n} e^{-\kappa K}) \right. \\ &\quad \left. - \bar{\Omega}_{\bar{i}_1\dots\bar{i}_n} \bar{\partial}^{\bar{i}_1} (\bar{s}_{\bar{\alpha}_1} s_{\beta_1} e^{-\kappa K}) \dots \bar{\partial}^{\bar{i}_n} (\bar{s}_{\bar{\alpha}_n} s_{\beta_n} e^{-\kappa K}) \right), \end{aligned}$$

with $\partial^i = g^{i\bar{j}} \bar{\partial}_j$ and $\bar{\partial}^{\bar{i}} = g^{\bar{i}j} \partial_j$. If $\text{Herm}(\mathcal{H}_\kappa)$ is the space of hermitian matrices in \mathcal{H}_κ and $\text{Comm}(\oplus^n \text{Herm}(\mathcal{H}_\kappa))$ is the space of n mutually commuting tuples of hermitian matrices in \mathcal{H}_κ , we can write the map as $\mathcal{I}: \text{Comm}(\oplus^n \text{Herm}(\mathcal{H}_\kappa)) \rightarrow \text{Herm}(\mathcal{H}_\kappa)$. Therefore, one can use the kernel of \mathcal{I} to approximate special Lagrangian submanifolds as the level sets of the n functions “ $\langle \tilde{\Omega}_{x,\kappa} | \ker(\mathcal{I}) | \tilde{\Omega}_{x,\kappa} \rangle$ ”.

Also, one can generalize this quantum system by coupling the particle to a rank r holomorphic vector bundle $V \rightarrow M$. We will not give many details of this generalization here, although we will say a few words. For instance, the system can be interpreted as a particle endowed with certain $U(r)$ -charge. The associated quantum Hilbert space is $H^0(M, V \otimes \mathcal{L}^{\otimes \kappa})$. One can also define an analogous set of coherent states and an associated distortion function. In the semiclassical limit, requiring the generalized distortion function to be constant as a function of M gives rise to generalized balanced metrics, and therefore, to hermite–Yang–Mills metrics on $V \rightarrow M$ when $\kappa^{-1} = 0$ [10].

Finally, as a technical comment, the *balanced metric* equations (4) and (3) can be explicitly solved for finite κ , and its solutions used to approximate Ricci-flat metrics and hermitian Yang–Mills connections. A method to solve them involves the concepts of T-map and algebraic Monte-Carlo integration [9, 11], which can be applied whenever one has enough analytical control on

the Kodaira's embeddings $M \hookrightarrow \mathbb{P}H^0(M, \mathcal{L}^{\otimes \kappa})$. We leave the problem of developing technical methods for constructing special Lagrangian submanifolds and other geometric objects for future work. In the following sections we will show how the concept of *balanced metric* appears naturally in other frameworks for quantization (Berezin's star product and path integral quantization), and thus gives rise to Kähler–Einstein metrics in the classical limit.

3 Berezin's star product

Instead of quantizing the space of observables by introducing a Hilbert space of states, \mathcal{H}_κ , and its corresponding space of quantum observables (i.e., the hermitian matrices), one can understand quantization as a noncommutative deformation of the geometry of M . In the deformation quantization approach to noncommutative geometry, the ordinary algebra of functions $C^\infty(M)$ is replaced by the noncommutative \star algebra $C^\infty(M)[[\kappa^{-1}]]$, which reflects the operator algebra of hermitian operators on \mathcal{H}_κ . The \star product of two elements in $C^\infty(M)[[\kappa^{-1}]]$ is defined through formal series expansions in powers of κ^{-1} , such that,

$$[f, g] := f \star g - g \star f = i\kappa^{-1}\{f, g\}_{PB} + O(\kappa^{-2}).$$

The explicit form of the algebra is not unique [16], in the same way that the quantization of a classical system is not unique. Here, we will first explore the Reshetikhin–Takhtajan star product in Kähler geometry [20].

To describe this algebra, we first introduce the diagonal of the Bergman kernel and the Calabi's diastatic function. Using the notation introduced above, the diagonal of the Bergman kernel can be written as

$$e(z, \bar{z}) = \sum_{\alpha} \bar{s}_{\alpha}(\bar{z}) s_{\alpha}(z) \exp(-\kappa K(z, \bar{z})),$$

which coincides with the distortion function defined in (2). The Calabi function is simply

$$\phi(z, \bar{z}; v, \bar{v}) = K(z, \bar{v}) + K(v, \bar{z}) - K(z, \bar{z}) - K(v, \bar{v}).$$

Note that $e(z, \bar{z})$ and $\phi(z, \bar{z}; v, \bar{v})$ are invariant under Kähler transformations $K \rightarrow K + f + \bar{f}$. Using the Berezin's formula, one can define a non-normalized product given by

$$(f \bullet g)(z, \bar{z}) := \int_M f(z, \bar{v}) g(v, \bar{z}) \exp(-\kappa \phi(z, \bar{z}; v, \bar{v})) \frac{\omega^n}{n!},$$

which can be used to introduce the normalized product

$$(f \star g)(z, \bar{z}) = \int_M f(z, \bar{v}) g(v, \bar{z}) \frac{e(z, \bar{v}) e(v, \bar{z})}{e(z, \bar{z})} \exp(-\kappa \phi(z, \bar{z}; v, \bar{v})) \frac{\omega^n}{n!}.$$

The Calabi's diastatic function is defined in some neighborhood of the diagonal $M \times M$, and the point $v = z$ is a critical point of the Calabi function considered as a function of v and \bar{v} ; the Laplace expansion of $e^{-\kappa \phi}$ at the critical point $v = z$ yields a formal power series in κ^{-1} . As it is shown in [20], one can determine naturally the \bullet product as a combinatoric expansion in powers of κ^{-1} , derived from the Laplace expansion of the diastatic function. Therefore, one has to compute the \bullet product in order to determine the normalized \star product. The unit element of their noncommutative deformation $C^\infty(M)[[\hbar]]$ given by the \bullet product is the diagonal of the Bergman kernel $e(z, \bar{z})$.

Therefore, as a corollary, if the unit element of the Reshetikhin and Takhtajan algebra is constant, i.e. the corresponding Bergman kernel has a constant diagonal, the metric on M is balanced. This shows how balanced metrics become natural objects in deformation quantization. One can study this phenomenon further in the path integral quantization formalism.

4 Completely degenerated quantum systems

In this section we compute the quantum vacuum energy density associated to a constant Hamiltonian function on M , in the semiclassical limit, $\hbar = \kappa^{-1} \rightarrow 0$. In the geometric quantization framework, the quantum Hamiltonian associated with the classical Hamiltonian function $\mathbf{1}: M \rightarrow 1$, is the identity operator Id ; if we identify the semiclassical vacuum states with the coherent states, the semiclassical vacuum energy density will be proportional to $\langle \tilde{\Omega}_x | \tilde{\Omega}_x \rangle$. However, in the path integral approach, the Hamiltonian is set to be zero, and the choice of vacuum is not necessarily the same as the identification “coherent state” = “vacuum state.”

By subtracting the classical energy density to $\langle \tilde{\Omega}_x | \tilde{\Omega}_x \rangle$, we will compare the path integral approach and the geometric quantization approach, and find that the leading term in κ^{-1} is the same, though the first sub-leading correction is not. This means that requiring the semiclassical vacuum energies (in both quantization frameworks) to be constant, yields metrics on M that become Kähler–Einstein in the classical limit. The fact that the sub-leading corrections are different only affects higher corrections to the aforementioned metrics when κ^{-1} , though small, it is not zero.

4.1 Vacuum energy in geometric quantization

The system is completely degenerated when the Hamiltonian function is constant; each point in the phase space is a *classical vacuum state* and the quantum Hilbert space becomes the space of *quantum vacua*. On the *geometric quantization* side, one identifies the quantum Hilbert space \mathcal{H}_κ with the space of holomorphic sections $H^0(M, \mathcal{L}^{\otimes k})$. The natural candidate to be the semiclassical quantum vacuum state peaked at x is the coherent state introduced by Rawnsley [19], and denoted by $|\tilde{\Omega}_x\rangle$. We construct $|\tilde{\Omega}_x\rangle$ as follows: first, we choose an orthonormal basis of holomorphic sections, $\{s_\alpha \in H^0(\mathcal{L}^{\otimes k})\}_1^{N(\kappa)}$ with

$$\langle s_\alpha | s_\beta \rangle = \delta_{\bar{\alpha}\beta} = \int_M \bar{s}_\alpha(\bar{x}) s_\beta(x) e^{-\kappa K(x, \bar{x})} \frac{\omega^n(x, \bar{x})}{n!},$$

where $s_\alpha(x) e^{-\kappa K(x, \bar{x})/2}$ is the complex number associated with the evaluation of the holomorphic section s_α at $x \in U$, and defined in the trivialization $\mathcal{L}^{\otimes k}|_U \simeq \mathbb{C} \times U$. Second and lastly, one can define the *coherent state* peaked at $x \in M$ as the ray in $\mathbb{P}\mathcal{H}_\kappa$ generated by

$$|\tilde{\Omega}_x\rangle := \sum_{\alpha=1}^{N(\kappa)} s_\alpha(x) \exp(-\kappa K(\bar{x}, x)/2) |s_\alpha\rangle \in \mathcal{H}_\kappa, \quad x \in U \subset M,$$

and one can easily show how such a ray is independent of the choice of trivialization of the line bundle.

The set of coherent states $\{|\tilde{\Omega}_x\rangle\}_{x \in M}$ is a supercomplete system of vectors in \mathcal{H}_κ , parametrized by the points of M . It also defines an embedding of M into $\mathbb{P}\mathcal{H}_\kappa$, and implies the Parseval identity (1). This allows the definition of an embedding of the space of quantum observables in \mathcal{H}_κ (i.e., the self-adjoint matrices in $\text{Herm}(\mathcal{H}_\kappa) \subset \mathcal{H}_\kappa^* \otimes \mathcal{H}_\kappa$) into the space of classical observables $C^\infty(M)$, according to the formula

$$\hat{f} \mapsto \langle \tilde{\Omega}_\circ | \hat{f} | \tilde{\Omega}_\circ \rangle = f \in C^\infty(M), \quad \hat{f} = \hat{f}^\dagger,$$

where \circ denotes the pre-image of f in M . The function f is called a *covariant symbol* of the matrix \hat{f} . A function $\check{f} \in C^\infty(M)$ such that the matrix \hat{f} is representable as

$$\hat{f} = \int_M |\tilde{\Omega}_x\rangle \otimes \langle \tilde{\Omega}_x | \frac{\check{f} \omega^n(x, \bar{x})}{n!},$$

is called *contravariant* symbol of the matrix \hat{f} . The map $\check{f} \mapsto \hat{f}$ is also known as *Toeplitz map*, $T: C^\infty(M) \rightarrow \text{Herm}(\mathcal{H}_\kappa) \subset \mathcal{H}_\kappa^* \otimes \mathcal{H}_\kappa$.

It is important to stress that the identification between the *quantum vacuum state* $|\Omega_x\rangle$ localized at $x \in M$ and the *coherent state* $|\tilde{\Omega}_x\rangle$ is, in somehow, made arbitrarily. Such an identification is motivated by the fact that the coherent state is peaked at x and localized within a neighborhood $V_x \subset M$ with minimal quantum uncertainty. More precisely, the coherent state $|\tilde{\Omega}_{x,\kappa}\rangle$ satisfies

$$\frac{1}{\langle \tilde{\Omega}_{x,\kappa} | \tilde{\Omega}_{x,\kappa} \rangle} \int_{V_x \subset M} \langle \tilde{\Omega}_{x,\kappa} | \tilde{\Omega}_{y,\kappa} \rangle \langle \tilde{\Omega}_{y,\kappa} | \tilde{\Omega}_{x,\kappa} \rangle \frac{\omega^n(y, \bar{y})}{n!} \sim 1, \quad (5)$$

with $\int_{V_x} \omega^n / \int_M \omega^n \sim \frac{1}{N}$. Such an identification is correct as a first approximation in κ^{-1} , although the $O(\kappa^{-2})$ terms are not universal and depend on the choice of vacuum state $|\Omega_{x,\kappa}\rangle$. The $O(\kappa^{-2})$ corrections are important at the time of computing correlation functions of the type

$$\langle \Omega_{x,\kappa} | \hat{f}_1 \hat{f}_2 \cdots \hat{f}_m | \Omega_{x,\kappa} \rangle \quad (6)$$

in the limit $\kappa \rightarrow \infty$, as power series in κ^{-1} of the covariant symbols $f_1, f_2, \dots, f_m \in C^\infty(M)[[\kappa^{-1}]]$. For instance, every identification of the vacuum state with peaked states that obey equation (5), gives rise to the same semiclassical limit

$$\langle \Omega_{x,\kappa} | [\hat{f}, \hat{g}] | \Omega_{x,\kappa} \rangle = i\kappa^{-1} \omega^{i\bar{j}} \left(\partial_i f(x, \bar{x}) \bar{\partial}_{\bar{j}} g(x, \bar{x}) - \partial_i g(x, \bar{x}) \bar{\partial}_{\bar{j}} f(x, \bar{x}) \right) + O(\kappa^{-2}),$$

with $f(x, \bar{x}) := \langle \Omega_{x,\kappa} | \hat{f} | \Omega_{x,\kappa} \rangle$ and $g(x, \bar{x}) := \langle \Omega_{x,\kappa} | \hat{g} | \Omega_{x,\kappa} \rangle$, [4]. However, the higher corrections $O(\kappa^{-2})$ will depend on the choice of vacuum state.

To compute the semiclassical limit of the correlators (6) beyond $O(\kappa^{-1})$ is a difficult task which involves hard analysis; see [18] for the most recent results. For simplicity, we study only the vacuum expectation value of the identity operator using the naïve vacuum state $|\tilde{\Omega}_{x,\kappa}\rangle$. Z. Lu computed the lower order terms in powers of κ^{-1} of the squared norm of the naïve vacuum state, [18],

$$\langle \tilde{\Omega}_{x,\kappa} | \tilde{\Omega}_{x,\kappa} \rangle = 1 + \frac{1}{2\kappa} R + \frac{1}{3\kappa^2} \left(\Delta R + \frac{1}{8} (|\text{Riemann}|^2 - 4|\text{Ricci}|^2 + 3R^2) \right) + O(\kappa^{-3}).$$

Computing the asymptotic series of the vacuum energy on the path integral side involves perturbative expansions of Feynman vacuum diagrams. As the classical energy density is set to be zero in the path integral formalism, one should compare the path integral result to the “renormalized” geometric quantized vacuum energy

$$\begin{aligned} E_0(x) &= \langle \tilde{\Omega}_{x,\kappa} | \tilde{\Omega}_{x,\kappa} \rangle - 1 \\ &= \frac{1}{2\kappa} R + \frac{1}{3\kappa^2} \left(\Delta R + \frac{1}{8} (|\text{Riemann}|^2 - 4|\text{Ricci}|^2 + 3R^2) \right) + O(\kappa^{-3}), \end{aligned} \quad (7)$$

which is zero at $\kappa = \infty$.

4.2 Path integral derivation of the vacuum energy

On the *path integral quantization* side, Cattaneo and Felder [6] give a prescription for computing correlation functions for quantized observables $f, g \in C^\infty(M)[[\kappa^{-1}]]$, by evaluating path integrals perturbatively as formal expansions in powers of κ^{-1} . In such perturbative expansion one considers perturbations around the constant map, i.e., the solution of the equations of motion or *classical vacuum state* $\Phi_0: \mathbb{R} \mapsto x \in M$. For simplicity, we choose a local coordinate chart around x , $\{\phi_i\}_{0 < i \leq n}$ given by the Kähler–Riemann normal coordinates [1]. For a vanishing

Hamiltonian, the phase-space action associated with perturbations Φ around the classical vacuum state Φ_0 is the line integral of the $U(1)$ -connection on the prequantum bundle $\mathcal{L}^{\otimes k}$, along the path Φ in M

$$S[\Phi] = i \int_{-\infty}^{\infty} dt \bar{\partial}_{\bar{j}} K(\phi, \bar{\phi}) \frac{d\bar{\phi}^{\bar{j}}}{dt}, \quad (8)$$

with $\Phi \in \text{Maps}(\mathbb{R} \rightarrow M)$ and⁴ $\Phi(\pm\infty) = x$, implying $\phi(\pm\infty) = 0$ in the local Kähler–Riemann normal coordinate system around x . The functional integration of fluctuations around the classical vacuum $x \in M$ defines a semiclassical quantum vacuum state that we denote as $|\Omega_{x,\kappa}\rangle$, although we don't know how to describe it as an element of the Hilbert space, \mathcal{H}_κ .

The prescription for computing the correlation functions that appear in deformation quantization [6, 17] is given by the path integral on the phase-space variables

$$\langle \Omega_x | \hat{f} \hat{g} | \Omega_x \rangle := f \star g(x, \bar{x}) = \int_{\text{Maps}(\mathbb{R} \rightarrow M) | \Phi(\pm\infty) = x} d\Phi f(\Phi(1)) g(\Phi(0)) \exp(i\kappa S[\Phi]), \quad (9)$$

with $f, g \in C^\infty(M)[[\kappa^{-1}]]$. In Riemann normal coordinates we can write the action (8) as follows

$$\begin{aligned} i\kappa S[\Phi] = & -\kappa \int_{\mathbb{R}} dt \bar{\partial}_{\bar{j}} K(\phi, \bar{\phi}) \frac{d\bar{\phi}^{\bar{j}}}{dt} = -\kappa \int_{\mathbb{R}} dt \left(g_{i\bar{j}}(x, \bar{x}) \phi^i \dot{\bar{\phi}}^{\bar{j}} + \frac{1}{2} R_{i\bar{j}k\bar{l}} \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} \right. \\ & + \frac{1}{6} D_m R_{i\bar{j}k\bar{l}} \phi^m \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} + \frac{1}{6} \bar{D}_{\bar{m}} R_{i\bar{j}k\bar{l}} \bar{\phi}^{\bar{m}} \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} + \frac{1}{12} D_n D_m R_{i\bar{j}k\bar{l}} \phi^n \phi^m \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} \\ & + \frac{1}{12} \bar{D}_{\bar{n}} \bar{D}_{\bar{m}} R_{i\bar{j}k\bar{l}} \bar{\phi}^{\bar{n}} \bar{\phi}^{\bar{m}} \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} + \frac{1}{12} \bar{D}_{(\bar{n}} D_m R_{i\bar{j}k\bar{l})} \phi^m \bar{\phi}^{\bar{n}} \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} \\ & \left. + \frac{1}{4} g^{o\bar{r}} R_{o(\bar{j}m\bar{l}} R_{i\bar{n}k\bar{r}} \phi^m \bar{\phi}^{\bar{n}} \phi^i \bar{\phi}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} + O(\phi^7) \dots \right), \end{aligned}$$

where $\dot{\phi} = d\phi/dt$, and the parentheses enclosing indices indicate the completely symmetric part of such indices; we sum over repeated indices. Still, the measure $d\Phi$ in the functional integration (9) also depends of the phase-space coordinate field ϕ . Hence, in this choice of coordinates

$$e^{-iE'_0(x)\delta(0)} = \int_{\text{Maps}(\mathbb{R} \rightarrow M) | \Phi(\pm\infty) = x} \prod_{i=1}^n d\phi^i d\bar{\phi}^{\bar{i}} \det \omega(\phi, \bar{\phi}) \exp\left(-\kappa \int_{\mathbb{R}} dt \bar{\partial}_{\bar{j}} K(\phi, \bar{\phi}) \frac{d\bar{\phi}^{\bar{j}}}{dt}\right), \quad (10)$$

where $\det \omega$ is the determinant of the Kähler form $\omega_{i\bar{j}}$, and $E'_0(x)$ is the quantum vacuum energy density, depending on the choice of semiclassical vacuum labeled as $x \in M$. Therefore, as ω depends on the integration variables, we can introduce an anti-commuting auxiliary field λ to write the path integral using a standard gaussian measure

$$e^{-iE'_0(x)\delta(0)} = \int \prod_{i=1}^n d\phi^i d\bar{\phi}^{\bar{i}} d\lambda^i d\bar{\lambda}^{\bar{i}} \exp\left(-\kappa \int_{\mathbb{R}} dt \bar{\partial}_{\bar{j}} K(\phi, \bar{\phi}) \frac{d\bar{\phi}^{\bar{j}}}{dt} + \int_{\mathbb{R}} dt \omega(\phi, \bar{\phi})_{i\bar{j}} \lambda^i \bar{\lambda}^{\bar{j}}\right),$$

where the functional integral of the auxiliary field λ obeys the rules of the Grassmann integration. One can expand the action for the auxiliary field, in powers of the field ϕ , to find out the interactions between auxiliary field and phase-space coordinate field,

$$\int_{\mathbb{R}} dt \omega(\phi, \bar{\phi})_{i\bar{j}} \lambda^i \bar{\lambda}^{\bar{j}} = i \int_{\mathbb{R}} dt \left(g_{i\bar{j}} \lambda^i \bar{\lambda}^{\bar{j}} + R_{i\bar{j}k\bar{l}} \lambda^i \bar{\lambda}^{\bar{j}} \phi^k \dot{\bar{\phi}}^{\bar{l}} + \frac{1}{12} \bar{D}_{(\bar{n}} D_m R_{i\bar{j}k\bar{l})} \lambda^i \bar{\lambda}^{\bar{j}} \phi^m \bar{\phi}^{\bar{n}} \phi^k \dot{\bar{\phi}}^{\bar{l}} \right)$$

⁴We denote by $\text{Maps}(\mathbb{R} \rightarrow M)$ the functional space of maps of the real line \mathbb{R} to the phase space M .

$$+ \frac{1}{4} g^{o\bar{r}} R_{o(\bar{j}m\bar{l}} R_{i\bar{n}k)\bar{r}} \lambda^i \bar{\lambda}^{\bar{j}} \phi^m \bar{\phi}^{\bar{n}} \phi^k \bar{\phi}^{\bar{l}} + \dots \Big),$$

where the coefficients $g_{i\bar{j}}$, $R_{i\bar{j}k\bar{l}}$, etc., are evaluated at $x \in M$.

Therefore, we can evaluate $E'_0(x)$ perturbatively as an expansion of the path integral in powers of κ^{-1} , in the limit $\kappa \rightarrow \infty$. If we write the Fourier transform of the field to the momentum variables as

$$\begin{aligned} \hat{\phi}(p) &= \frac{1}{2\pi} \int_{\mathbb{R}} dt \exp(ipt) \phi(t), & \phi(\pm\infty) &= 0, \\ \hat{\lambda}(p) &= \frac{1}{2\pi} \int_{\mathbb{R}} dt \exp(ipt) \lambda(t), & \lambda(\pm\infty) &= 0, \end{aligned}$$

the propagators in the momentum space are

$$\bullet \xrightarrow[\underline{p-i\varepsilon}]{\frac{ig^{i\bar{j}}}{p-i\varepsilon}} \bullet \qquad \bullet \xrightarrow{-ig^{i\bar{j}}} \bullet$$

Figure 1. Propagators for the phase-space coordinate field (left), and the auxiliary field (right).

In order to compute (10), we perform a perturbative expansion in powers of $\kappa^{-1} = \hbar$. We can compute the vacuum energy $E'_0(x)$, by simply summing the connected vacuum (or bubble) diagrams, and dividing by the total length of \mathbb{R} . Thus, a vacuum diagram with L loops contributes to $E'_0(x)$ a term proportional to $\kappa^{1-L} = \kappa^{V-P}$, with V the *number of vertices* and P the *number of propagators*. Therefore, to determine $E'_0(x)$ up to order κ^{-2} , we have to sum the connected diagrams depicted in Figs. 4-10.

$$\begin{aligned} \begin{array}{c} \nearrow \bar{j} \\ \searrow k \\ \nwarrow \bar{l} \\ \nearrow i \end{array} &= -ip_{\bar{l}} R_{i\bar{j}k\bar{l}} & \begin{array}{c} \nwarrow \bar{j} \\ \nearrow i \\ \leftarrow \bar{n} \\ \rightarrow m \\ \nwarrow \bar{l} \\ \nearrow k \end{array} &= -\frac{i}{4} p_{\bar{l}} (\bar{D}_{(\bar{n}} D_m R_{i\bar{j}k\bar{l}}) + 3g^{o\bar{r}} R_{o(\bar{j}m\bar{l}} R_{i\bar{n}k)\bar{r}}) \end{aligned}$$

Figure 2. Interaction vertices for the phase-space field. $p_{\bar{l}}$ denotes the momentum carried by the particle which propagates along the \bar{l} -leg.

$$\begin{aligned} \begin{array}{c} \nwarrow \bar{j} \\ \nearrow k \\ \nwarrow \bar{l} \\ \nearrow i \end{array} &= iR_{i\bar{j}k\bar{l}} & \begin{array}{c} \nwarrow \bar{j} \\ \nearrow k \\ \leftarrow \bar{n} \\ \rightarrow m \\ \nwarrow \bar{l} \\ \nearrow i \end{array} &= i(\bar{D}_{(\bar{n}} D_m R_{i\bar{j}k\bar{l}}) + 3g^{o\bar{r}} R_{o(\bar{j}m\bar{l}} R_{i\bar{n}k)\bar{r}}) \end{aligned}$$

Figure 3. Interaction vertices for the auxiliary field with the phase-space field.

As we want only to evaluate diagrams up to order κ^{-2} , we only need to consider a few interactions; by drawing the diagrams, one realizes that the only vertices that appear are the ones depicted in Figs. 2 and 3. The asymptotic expansion of $E'_0(x)$ in powers of κ^{-1} can be expressed as

$$-iE'_0(x)\delta(0) = \sum_{\Gamma \in \mathfrak{G}_2} \frac{1}{\kappa |\text{Aut}(\Gamma)|} D_{\Gamma}(x) + \sum_{\Gamma \in \mathfrak{G}_3} \frac{1}{\kappa^2 |\text{Aut}(\Gamma)|} D_{\Gamma}(x) + O(\kappa^{-3}), \quad (11)$$

Figure 4. Two-loop vacuum diagrams, (2.i) left and (2.ii) right.

Figure 5. Three-loop vacuum diagram (3.i).

where \mathfrak{G}_L is the set of bubble diagrams with L loops, $\text{Aut}(\Gamma)$ is the subgroup of the group of automorphisms of Γ that maps vertices to vertices of the same type and oriented propagators to oriented propagators of the same type (which start and end at the same vertices), $|\text{Aut}(\Gamma)| = \#\text{Aut}(\Gamma)$ is also known as *symmetry factor*, and $D_\Gamma(x)$ is the evaluation of the Feynman diagram.

The evaluation of each diagram $D_\Gamma(x)$ follows from the Feynman rules in momentum space: to each line we associate its corresponding propagator (Fig. 1), to each vertex we associate its corresponding numerical factor (Figs. 2 and 3), we impose momentum conservation at each vertex and integrate over each undetermined momentum $\int_{\mathbb{R}} \frac{dp}{2\pi}$. There are two types of integrals that appear in the evaluation of bubble diagrams

$$\lim_{\varepsilon \rightarrow 0^+} \frac{1}{2\pi} \int_{\mathbb{R}} \frac{idp}{p - i\varepsilon} = \frac{1}{2} \quad \text{and} \quad \delta(0) = \frac{1}{2\pi} \int_{\mathbb{R}} dp.$$

Each vacuum diagram is proportional to the Dirac delta $\delta(0)$, or the “total length” of \mathbb{R} , because the calculation in the momentum space yields the total vacuum energy in \mathbb{R} . As we are just interested in the vacuum energy *density*, we will divide out by infinite total length of the $(0+1)$ -spacetime, \mathbb{R} . Thus, in order to determine $E'_0(x)$ up to three loops, we use equation (11). The evaluation of the two- and three-loop diagrams gives rise to the following: for two-loops,

- (2.i) in Fig. 4

$$D_{(2.i)}(x) = -iR_{i\bar{j}k\bar{l}}g^{i\bar{j}}g^{k\bar{l}} \frac{1}{(2\pi)^2} \int_{\mathbb{R}} dp_1 \frac{ip_1}{p_1 - i\varepsilon} \int_{\mathbb{R}} dp_2 \frac{i}{p_2 - i\varepsilon} = \delta(0) \frac{1}{2} R.$$

- (2.ii) in Fig. 4

$$D_{(2.ii)}(x) = iR_{i\bar{j}k\bar{l}} \frac{1}{(2\pi)^2} \int_{\mathbb{R}} dp_1 (-i)g^{k\bar{l}} \int_{\mathbb{R}} dp_2 \frac{ig^{i\bar{j}}}{p_2 - i\varepsilon} = \delta(0) \frac{1}{2} R.$$

For three-loop diagrams,

- (3.i) in Fig. 5

$$\begin{aligned} D_{(3.i)} &= (-i)^2 R_{i\bar{j}k\bar{l}} g^{i\bar{j}} R_{m\bar{n}o\bar{p}} g^{m\bar{n}} g^{k\bar{p}} g^{o\bar{l}} \int_{\mathbb{R}^3} \frac{dp_1 dp_2 dp_3}{(2\pi)^3} \frac{i}{p_1 - i\varepsilon} \left(\frac{i}{p_2 - i\varepsilon} \right)^2 p_2 \frac{ip_3}{p_3 - i\varepsilon} \\ &= \delta(0) \frac{1}{4} |\text{Ricci}|^2. \end{aligned}$$

Figure 6. Three-loop vacuum diagram (3.ii).

Figure 7. Three-loop vacuum diagram (3.iii).

- (3.ii) in Fig. 6

$$\begin{aligned}
 D_{(3.ii)} &= (-i)^2 R_{i\bar{j}k\bar{l}} R^{i\bar{j}k\bar{l}} \int_{\mathbb{R}^4} \frac{dp_1 dp_2 dp_3 dp_4}{(2\pi)^4} \delta(p_1 + p_3 - p_2 - p_4) p_1 p_2 \\
 &\quad \times \frac{i}{p_1 - i\varepsilon} \frac{i}{p_2 - i\varepsilon} \frac{i}{p_3 - i\varepsilon} \frac{i}{p_4 - i\varepsilon} \\
 &= -|\text{Riemann}|^2 \int_{\mathbb{R}^3} \frac{dp_1 dp_2 dp_3}{(2\pi)^3} \frac{1}{(p_3 - i\varepsilon)[(p_1 + p_3 - p_2) - i\varepsilon]} \\
 &= -|\text{Riemann}|^2 \int_{\mathbb{R}^3} \frac{dl_1 dl_2 dl_3}{(2\pi)^3} \frac{i}{(l_1 - i\varepsilon)(l_2 - i\varepsilon)} = \delta(0) \frac{1}{4} |\text{Riemann}|^2,
 \end{aligned}$$

where $l_1 = p_1 + p_2 - p_3$, $l_2 = p_3$ and $l_3 = p_2$.

- (3.iii) in Fig. 7

$$\begin{aligned}
 D_{(3.iii)} &= \frac{-i}{4} \left(\Delta R + 3 \left(\frac{2}{3} |\text{Ricci}|^2 + \frac{1}{3} |\text{Riemann}|^2 \right) \right) \\
 &\quad \times \lim_{\varepsilon \rightarrow 0^+} \int_{\mathbb{R}^3} \frac{dp_1 dp_2 dp_3}{(2\pi)^3} \frac{i}{p_1 - i\varepsilon} \frac{i}{p_2 - i\varepsilon} \frac{ip_3}{p_3} \\
 &= \delta(0) \frac{1}{16} (\Delta R + 2|\text{Ricci}|^2 + |\text{Riemann}|^2).
 \end{aligned}$$

- (3.iv) in Fig. 8. Similarly to (3.i)

$$D_{(3.iv)} = \delta(0) \frac{1}{4} |\text{Ricci}|^2.$$

- (3.v) in Fig. 8

$$D_{(3.v)} = \delta(0) \frac{1}{4} |\text{Ricci}|^2.$$

Figure 8. Three-loop vacuum diagrams with auxiliary field, (3.iv) left and (3.v) right.

Figure 9. Three-loop vacuum diagram with auxiliary field (3.vi).

Figure 10. Three-loop vacuum diagram with auxiliary field (3.vii).

- (3.vi) in Fig. 9. Similarly to (3.ii),

$$\begin{aligned} D_{(3.vi)} &= (iR_{i\bar{m}k\bar{o}})(iR_{n\bar{j}p\bar{l}})(-ig^{i\bar{j}})(-ig^{k\bar{l}}) \int_{\mathbb{R}^3} \frac{dp_1 dp_2 dp_3}{(2\pi)^3} \frac{ig^{n\bar{m}}}{p_1 - i\varepsilon} \frac{ig^{p\bar{o}}}{p_2 - i\varepsilon} \\ &= \delta(0) \frac{1}{4} |\text{Riemann}|^2. \end{aligned}$$

- (3.vii) in Fig. 10. Similarly to (3.iii),

$$\begin{aligned} D_{(3.vii)} &= i \left(\Delta R + 3 \left(\frac{2}{3} |\text{Ricci}|^2 + \frac{1}{3} |\text{Riemann}|^2 \right) \right) \int_{\mathbb{R}^3} \frac{dp_1 dp_2 dp_3}{(2\pi)^3} \frac{i}{p_1 - i\varepsilon} \frac{i}{p_2 - i\varepsilon} \\ &= \delta(0) \frac{1}{4} (\Delta R + 2|\text{Ricci}|^2 + |\text{Riemann}|^2). \end{aligned}$$

Finally, including the *symmetry factors* of each diagram, and summing them as in equation (11), yields the vacuum energy density associated to the semiclassical vacuum state localized at $x \in M$,

$$E'_0(x) = \frac{1}{2\kappa} R + \frac{1}{96\kappa^2} (5\Delta R + 42|\text{Ricci}|^2 + 17|\text{Riemann}|^2) + O\left(\frac{1}{\kappa^3}\right). \quad (12)$$

Thus, comparing equation (12) with the equivalent result in geometric quantization (7), yields different vacuum energy densities $E_0(x) \neq E'_0(x)$, despite the fact that the leading terms are identical. The corollary is an interesting one: fixing κ and requiring the quantum vacuum energy density to be constant on the quantum moduli space of semiclassical vacua is equivalent to endowing M with a “generalized balanced metric”. This generalized notion of balanced metric gives rise to the same Kähler–Einstein metrics in the classical limit, which shows that the emergence of Kähler–Einstein metrics in the classical limit is generic for a broad choice of semiclassical vacuum states.

5 Conclusion

We have shown how the Kähler–Einstein metrics appear naturally in the classical limit of Kähler quantization. In geometric quantization, identifying semiclassical vacuum states with coherent states allows us to define balanced metrics as those metrics which yield constant semiclassical vacuum energy (for constant classical Hamiltonian). In the Berezin’s approach to deformation quantization, the unit element of the noncommutative algebra $C^\infty(M)[[\hbar^{-1}]]$ is the constant function, if and only if the metric is balanced. Also in path integral quantization, requiring the semiclassical vacuum energy to be constant yields a metric that is Kähler–Einstein in the classical limit.

Strictly speaking, the metrics that appear in path integral quantization are not balanced. This is due to a different choice of vacuum states in the path integral formalism; thus, for each choice of moduli spaces of semiclassical vacua one can define different *generalized balanced metrics*. It would be interesting to study the properties exhibited by this general class of metrics. For instance, it is especially interesting to understand how introducing quantum corrections to the Kähler potential deforms the moduli of semiclassical vacua [16].

Another interesting problem would be to understand balanced metrics in vector bundles within the framework of Kähler quantization. Also, one could explicitly construct special Lagrangian submanifolds in Calabi–Yau threefolds, and give a *geometric quantization* formulation of the Bressler–Soibelman conjecture [5] (which conjectures a correspondence of the Fukaya category with a certain category of holonomic modules over the quantized algebra of functions).

A final motivation for future research comes from the fact that the geometric objects explored in this paper appear in the large volume limit of string theory compactifications. We have shown how these objects can be explicitly constructed in the semiclassical limit of geometric quantization; one would expect that different areas of string theory, such as Matrix theory, black holes, and Calabi–Yau compactification theory [3, 7, 13, 14], where the quantized algebra of functions plays a special role, could be understood better through a deeper study of the ideas explored here.

Acknowledgements

It is a pleasure to thank T. Banks, E. Diaconescu, M. Douglas, R. Karp, S. Klevtsov, and specially the author’s advisor G. Moore, for valuable discussions. We would like to thank as well G. Moore and G. Torroba for their comments on the manuscript, and J. Nannarone for kind encouragement and support. This work was supported by DOE grant DE-FG02-96ER40949.
